FlexBox Exercise and Video

Flex box is most useful for laying out A row of content. You first create a block container that will hold all the items that are to be displayed with flexbox. With CSS you select this outside container and use the display flex box. Using flex-wrap you can have the items in the flex box moved to a new row if they take up the entire width of the container.

Using the justify-content attribute you can specify how you would like the items to be spaced horizontally. They can be centered or move to the left or right, or they can be spread using space-around or a space-between. The align-items attribute is basically equivalent to justify-content but for the vertical direction. There is also an option to change the direction of the flex box with flexbox-direction. If the direction is changed all the other attributes affect the flex box container relative to the new direction.
